

CREATING A UNIVERSAL INFORMATION LANGUAGE

OSCAR BENDER-STONE

ABSTRACT. Welkin is a formalized programming language to store information. We introduce its use cases and rigorously define its syntax and semantics. From there, we introduce the bootstrap, making Welkin completely self-contained under a meta-theory based on combinators, equivalent to a provably minimal fragment of arithmetic.

1. INTRODUCTION

Information Management (IM) is an open area of research as a result of the depth and breadth of disciplines. In terms of depth, many areas are often specialized, requiring an immense understanding of the broader concepts involved and nomenclature used. This is evident in the sciences, as explored in [Fan13], [CF14]. Additionally, in terms of breadth, creating common representations shared across sub-disciplines can be difficult. In mathematics, for example, has extremely diverse disciplines, and connecting these areas is an open problem in scalability [Car+21]. Moreover, creating a standardized form across communities is challenging. In other subjects, like the social sciences, there are no standard terms, and the majority of cited references are books, which are not indexed by many databases [Arc+06]. More broadly, IM *itself* is divided from distinct approaches that lack interoperability [AJ23]. Some authors equate IM to Knowledge Management (KM) and assert that information must be true [Edw22]. These problems posed by broadly and faithfully capturing subjects demonstrate the enormous task of effective IM.

In attempt to address these challenges, several solutions have been proposed, but none completely fix these issues. In the sciences, a group of researchers created the Findable Accessible Interoperable Resuable (FAIR) guidelines [Wil+16]. Instead of providing a concrete specification or implementation, FAIR provides suggestions to encourage better storage of scientific information. However, multiple papers have outlined problems with these overarching principles, including missing checks on data

quality [Gui+25], missing expressiveness for ethics frameworks [Car+21], and severe ambiguities that affect implementations [Jac+20]. Along with the sciences, there are several proposals in mathematics, including QED project and the OpenLogic Project. ... While they have advanced storage for mathematical information, OpenLogic these project has focused primarily on logic ... These proposals, even focused on specific fields, fail to accommodate for all of the mentioned challenges.

In addition to these proposals, Burgin’s work on a theory of information [Bur09], [Bur09] comprehensively includes many separate areas for IM as a whole. He provides flexible definitions through a free parameter, an “infological system” that encompasses domain specific terminology and concepts. He then proceeds to mention many areas in the natural sciences, and connects his theory back to related mathematical studies, including Algorithmic Information Theory. Despite the large coverage of fields, Burgin does not closely tie the free parameter with his formal analysis, making it unclear how to use this in a practical implementation. Each of these proposals has severe shortcomings and highlights major obstacles for IM.

This thesis introduces a language to resolve these issues. I call this language **Welkin**, based on an old German word meaning cloud [Dic25]. The core result of this thesis is proving that Welkin is a) **universal**, b) **scalable**, and c) **standardized**, see Section 1.1. The core idea is to generalize Burgin’s free parameter and enable arbitrary representations in the theory, controlled by a computable system. The notion of representation builds on Peirce’s semiotics, or the study of the relationship between a symbol, the object it represents, and the interpreter or interpretation that provides it that meaning [Atk23]. Moreover, to address queries on the validity of truth, we use a relative notion that includes a context managed by a formal system. Truth can then be determined on an individual basis, providing flexibility to any discipline. The focus then shifts to the usefulness of representations based on a topological notion of “collapse” or “coherency”. This approach is inspired by coherentism, a philosophical position that states truth is determined in comparison to other truths. [Bra23]. We incorporate ideas from coherentism to identify which representations identify their corresponding objects, and we define information as an invariant under these coherent representations. We include definitions on a *working* basis as what is most practical, not an epistemological stance that can be further clarified in truth systems.

1.1. Goals.

- **Goal 1: Universal.** The language must include unspecified, user created parameters to accommodate for arbitrary concepts and ideas.
- **Goal 2: Scalable.** Local queries in the database, determining if there is enough “explicit” information, must be efficient. Certificates must be available to prove cases where optimal representations have been achieved.
- **Goal 3: Standardized.** The language needs a rigorous and formal specification. Moreover, the bootstrap must be formalized, as well as an abstract machine model. The grammar and bootstrap must be fixed to ensure complete forwards and backwards compatibility.

1.2. Organization.

- Section 2. Foundations: defines the meta-theory use and its connections to first-order logic and fragments of arithmetic.

- Section 3. Information Organization. Develops the optimal information system (w.r.t. to a metric defined in this system) to satisfy Goal 3.
- Section 4. Defines the syntax and semantics.
- Section 5. Bootstraps Welkin by proving that there is a Welkin node that contains enough information about the standard. Fulfills Goal 2 with both the Standard AND the complete bootstrap.
- Section ?. Prototype. Time permitting, develop a prototype to showcase the language, implemented in python with a GUI frontend (Qt) and possibly a hand-made LL(1) parser.
- Section 8. Conclusion. Reviews the work done in the previous sections. Then outlines several possible applications.

2. MOTIVATING EXAMPLE

3. SYNTAX

To keep this thesis self-contained, all recursive definitions are included. For simplicity, we will use the notation a_0, \dots, a_n for a finite list of items. We will revisit the notion “finite” more rigorously in Section 6.

Definition 3.0. The **alphabet of binary words** is $\mathcal{A}_{\text{bword}} ::= \text{bit} \mid . \mid w$, where $\text{bit} ::= 0 \mid 1$. A **binary word** is defined recursively: the symbols 0 or 1 are strings, or if w is a string, then so are $w.0$ and $w.1$. We set concatenation to be right-associative, i.e., $(w.w').w'' = w.(w'.w'')$, and safely abbreviate $w.w'$ as ww' . We write $w \in \text{bword}$ to denote that w is a binary word.

For simplicity, we extend the alphabet to include two common bases: decimal and hexadecimal.

Now, the base encoding for Welkin is in US-ASCII, formally defined below.

Definition 3.1. The **alphabet of words** $\mathcal{A}_{\text{word}} ::= \mathcal{A}_{\text{bword}} + \mathcal{A}_{\text{dec}} + \mathcal{A}_{\text{hex}}$, where:

- $\mathcal{A}_{\text{dec}} ::= 0 \mid 1 \mid 2 \mid 3 \mid 4 \mid 5 \mid 6 \mid 7 \mid 8 \mid 9$
- $\mathcal{A}_{\text{hex}} ::= A \mid B \mid C \mid D \mid E \mid F$

A **word** is a concatenation of either only binary digits, only decimal digits, or hexadecimal digits. Each of these are denoted with different prefixes: decimal has none, binary uses $0b$, and hexadecimal uses $0x$.

Using binary words simplifies the bootstrap, so while these digits are included, they are *defined* in terms of binary words, see Section 6.

Now, the base encoding for Welkin is in US-ASCII, formally defined below.

Definition 3.2. US-ASCII consists of 256 symbols, listed in Table ?.

We reserve the term **string** when a word is explicitly enclosed in delimiters, namely single or double quotes.

Now, we formalize an unambiguous form of EBNF for our use case.

Definition 3.3. BNF consists of productions. Writing $r := a_1 \mid \dots \mid a_n$ is shorthand for including the rules $r := a_1, \dots, r := a_n$.

EBNF additionally contains the following abbreviations:

- $r := a_1 \mid \dots \mid a_n$ is shorthand for including the rules $r := a_1, \dots, r := a_n$.

Welkin's grammar is displayed in ...

Definition 3.4. A grammar is LL(1) if ...

Theorem 3.5. *Welkin's grammar is LL(1). Hence, this grammar is unambiguous.*

4. SEMANTICS

4.1. ASTs.

- Semantics on ASTs
 - Terms: graphs
 - For ease of use, include a null node that is the root of the tree. This represents the module itself.
- For information organization: integrate with previous section
 - Emphasize how this is a useful tool and can ensure **new** information content is being created (at least, that can be distinguished from the current module). If already existing, but that doesn't match the user's expectations, they need to refine it! OR, maybe it **does** match similarly with something else! (e.g., hidden connections between math and music)
- Emphasize pragmatics as well, via units

4.2. Representations.

Now we develop the formal framework to discuss information in terms of units, enabling a complete mechanization of Welkin's meta-theory. To keep this section self-contained, we explicitly provide all recursive definitions.

Definition 4.2.0. The **alphabet of units** is $\mathcal{A}_{\text{unit}} = u \mid \mathcal{A}_{\text{word}}$. A **unit ID** is combination of symbols u_w , where $w \in \text{word}$.

Definition 4.2.1. A **free parameter** is a parameter given an associated ID. No further restrictions are imposed.

We now define representations recursively, using unit IDs and free parameters as the base case.

Definition 4.2.2. Units are recursively defined:

- **Base case:** IDs and free parameters are units.
- **Recursive step:**
 - **Parts::** if u_1, \dots, u_n are finitely many units, then so is their combination $\{u_1, \dots, u_n\}$. A combination defined without a provided ID is called an **anonymous unit**.
 - **Representations:** If u, w, v are units, so is $v \rightarrow u$. We say v **represents** u . or conversely, u is **represented by** v .

Key equalities:

- $u.\{\}$ = u . Acts as a sort of * operator from other languages.
 - To use one level up: $.u$
- $\left(u \xrightarrow{v} w\right) \in x \Leftrightarrow x(u) \xrightarrow{x(v)} x(w)$, where $x(u)$ is $x.u$ if $u \in x$ or u otherwise.

Example 4.2.3. Consider a house with a dog, a cat, and a person. We can represent the house as unit *house*, the dog as unit *dog*, the cat by unit *cat*, and the person by unit *person*. In our Welkin file, we add, *house* { *dog*, *cat*, *person*}. The person has an internal concept of pet and uses it to represent both the dog and cat, which we write as *person* { *animal* --> *dog*, *animal* --> *cat*}, under the scope of *house*.

Parts of units are denoted as $u.u'$. Scoping is included to provide namespaces. Moreover, parts enable **interpretations**. We write $u \xrightarrow{v} u'$ in case $u, v, (u \rightarrow v) \in u'$, so u represents v **via** u' . In this case, we say u' is a **context** to $u \rightarrow v$. Note that unlabeled representations can have multiple contexts.

Example 4.2.4. Consider the recursive definition of a binary tree: either it is a null (leaf) node, or it contains two nodes, left and right. We can model this as follows:

- First, create units for each of the notions: *tree* {*null*, *left*, *right*}.
- Next, we write, *tree* { *null* --> *.tree*, *.tree* --> *left*, *.tree* --> *right*, { *.left*, *.right* } --> *.tree*}. Notice that we refer to the *namespace*, thereby enabling recursion. By our scoping rules, writing *tree* would be a *new* unit.
- To impose that the left subtree is *distinct* from the right one, we can use symbols.

An important idea in this example is that the abstraction could be defined *first*, or a concrete model could. For this reason, the choice of how entities are represented is flexible.

Definition 4.2.5. A unit u is **non-trivial** if it is non-empty and does not contain all relations. A unit u is **coherent relative to a context** u' if $u + u'$, the union of these units, is non-trivial.

Remark 4.2.6. This definition is a natural generalization of consistency in first-order logic. We will frequently rely on this result throughout the thesis.

Theorem 4.2.7. *A representation is preserves information modulo \equiv iff the representation modulo \equiv is coherent.*

Remark 4.2.8. This theorem enables truth management via specific contexts, specified as units. The task of finding core truths is then free, left open to flexibility accommodate for any truth management.

Example 4.2.9. First Order Logic

4.3. Universal Systems.

Inspired by [Mes12], we prove that scoping is strictly more expressive than without.

Lemma 4.3.10. *Representations with interpretations are undefinable in terms of free representations.*

Theorem 4.3.11. *Any computable function and its trace can be represented by units.*

Proof. We prove there is a natural embedding from the lambda calculus into our meta-theory, using two parts:

- $\lambda x.f$ is represented as $\{x \rightarrow f\}$.
- $f.g$ is represented as the combination of units, or $\{f, g\}$.

Thus, any λ -term can be represented in the meta-theory, completing the proof. \square

Note that there are multiple ways to prove Theorem 4.3.4, infinitely in fact. This motivates the following definition.

Definition 4.3.12. A universal representation system is a unit that can represent any representation.

Theorem 4.3.13. *A unit is a universal representation system if and only if it can represent any partial computable function. Moreover, any universal representation system can represent any universal representation system. In particular, representing itself is called **reflection**.*

The term *universal* is specifically for expressing *representations* symbolically. The free parameter still needs to be included and is an additional feature on top of partial computable functions. However, the *management* of these symbols is done entirely with partial computable functions.

The next section discusses the issue of *managing* these infinite choices.

5. INFORMATION ORGANIZATION

- Main question: **which** universal system to choose? Is this practical?
 - What is a suitable criterion for a base theory?
 - Recall aim: want to mechanically store systems for a database
 - * What if possible performance degradation? Will we get stuck if we start with one architecture? Will we have to adjust later?
 - * Aim is to ensure architecture is completely flexible and can automatically adapt
 - * One key metric: ability to store as many systems coherently as possible, i.e., store as much information as possible
 - Main problem: Blum's speedup theorem
 - * Briefly generalize this for slate logic
 - * Show that no single way to completely organize systems based on a computable metric.
- This is part of the need for new search techniques!
- * Want to separate search from storage though, but we want to improve stored results **with** new results. This forms the idea behind the database architecture: have a simple way to store results that automatically gets better with new techniques/results.
 - * Need explicit proofs for this! Not sure how to store certificates...

5.1. Impossible Classes.

The reason to restrict our transformations is two-fold. First, we need to ensure we can *verify* them efficiently. Determining whether a morphism between two formal systems exist can be reduced to the Halting problem, and is therefore not practical for defining an optimal formal system. Second, if we include those transformations that we *can* effectively check, no optimal formal system exists.

Theorem 5.1.0. *With respect to the class of all computable transformations that can be computably verified, there is no optimal formal system.*

5.2. Efficient Querying.

Instead of making proofs most efficient as is, we want to support finding optimal representations. But we want to do this from an efficiently queryable system, which is the most optimal.

6. BOOTSTRAP

- Provided in bootstrap.welkin file or similar. Main module is welkin, which needs to:
 - Provide slates, so inductive definition of binary strings + variables
 - Explain combinators
 - Explain the basics of universal systems. This is very important!
 - * Can elide proofs IF there is enough information content.
 - * TODO: figure out how proofs might work in this setting
 - Provides syntax and semantics of Welkin itself
- This thesis: will prove that the AST generated from this file

is correct AND that it does, with a suitable interperation bootstrap itself.

- Explain how slates expand the envelope for implementations, BUT ensures that the final product, the syntax + semantics checkers and the information organization, can be externally seen!

7. CONCLUSION

- Review of thesis
 - Developed slate logic + bi-translation with FOL
 - Developed locally optimal organizational technique that can improve based on annotations/certificates
 - Introduced the language, with a straightforward graph syntax and semantics
 - Builds upon the last section
 - Bootstrapped standard + used coherency condition
- Significance
 - Backwards AND forwards compatbile standard that bootstraps itself. Easy for implementations!
 - Applications to any human subject
 - * Sciences
 - * Liberal arts
 - * Economics
 - * Etc.
- Future work
 - Programming language semantics + synthesis
 - * Incorporate broader aspects + intent of users! ESSENTIAL for new programming languages to be able to discuss pragmatics in some way!
 - * Also reproducible AND executable specifications, though creating an engine to execute these is far beyond the scope of the thesis
 - Organizing large corpuses of human text
 - Numerous applications to AI and improving results

* Emphasize role of symbol grounding problem in AI
